Introduction

A transportation problem can be described as a supply and demand problem. There is a specific supply of product available at specified location and a certain demand required at other locations. Delivery from each possible supplier to each demander also has a different cost associated with it. Hence, the goal is to minimize the cost while still transporting all required products.

Such a transportation problem is typically modeled in a node-like fashion (Figure 1). The suppliers are shown on the left and the demanders on the right. The cost associated with delivery is the connecting line. For calculation purposes, it is easier to represent this in a table (Figure 2). The suppliers and their values are shown on the left/right as "S-". The demanders are shown along the top/bottom as "D-". The costs associated with each delivery path are the cell intersecting an "S-" row and "D-" column.

For solving an feasible solution to a transportation problem, three methods will be discussed, as well as the limitation of minimum delivery.

The three methods are referred to as:

1. "North West Corner" approximation method
2. "Minimum Cost Element" approximation method
3. "Least Potentials" optimization method

A sample problem is provided (# 81) from appendix 1. This sample problem is solved manually to show the process of each of the three methods. Finally, a program is demonstrated for automatically solving by these same methods, and includes the limitation of "Minimum Delivery".

Method Verification

Balance Check

Before the transportation problem can be solved, the supply and demand must be checked such that they are balanced. This simply means that the available supply equals the amount demanded. If the problem is not balanced, additional fake rows must be added to account for the extra supply or demand.

$$isClosed = \begin{cases} true, & \sum S_i = \sum D_i \\ false, & \sum S_i <> \sum D_i \end{cases}$$

Example:

	D0	D1	D2	D3	D4	
S0	24	8	10	23	18	19
S1	19	1	11	9	6	14
S2	5	7	4	8	9	13
S3	6	13	3	15	5	18
	14	23	7	10	10	

Given the above problem table, we find the supply and demand to be equal. Hence the transportation problem is closed, and a solution can be computed.

$$\begin{aligned} Supply &= \sum S_i = 19 + 14 + 13 + 18 = 64 \\ Demand &= \sum D_i = 19 + 14 + 13 + 18 = 64 \\ Supply &= Demand \therefore \text{Balanced} \end{aligned}$$

Cost Computation

The total cost of delivery is calculated by multiplying the cost for each path by the number of products delivery on that path.

Example:

	D0	D1	D2	D3	D4	
S0	24	8	10	23	18	19
S1	19	1	11	9	6	14
S2	5	7	4	8	9	13
S3	6	13	3	15	5	18
	14	23	7	10	10	

$$\begin{aligned} Total\ Cost &= 24*14 + 8*5 + 1*14 + 7*4 + 4*7 + 8*2 + 15*8 + 5*10 \\ Total\ Cost &= 336 + 40 + 14 + 28 + 28 + 16 + 120 + 50 \\ Total\ Cost &= 632 \end{aligned}$$

Answer Check

The standard method to check the solution, is to compare the number of deliveries to the number of suppliers and delivers. The solution should meet the following criteria equation.

$$\#Deliveries = \#Suppliers + \#Demanders - 1$$

Example, using the previous table:

$$\begin{aligned} \#Deliveries &= 8, \#Suppliers = 4, \#Demanders = 5 \\ 8 &= 4 + 5 - 1 \therefore \text{True} \end{aligned}$$

Method Descriptions

North West Corner Approximation

This approximation is performed by continuously finding the most northwest cell of the table and picking the min between the supplier and demander for delivery. This process is repeated for the entire grid until all supply and demand is met.

Step 1 – Find most north west cell											<ol style="list-style-type: none"> 1. Locate the cell that is most north west. 2. Ensure there is available supply. 3. Ensure that is available demand.

Least Potentials Optimization

This method is an optimization method of an existing feasible solution. It calculates a penalty score for each cell. By reducing the penalty for each cell, the solution becomes optimized. This is reduced by identifying an adjustment loop, modifying by a specific amount, and repeating the process. When all penalties are zero or negative, the optimal solution has been found.

Step 1 – Create initial approximation						<ol style="list-style-type: none"> 1. Generate an initial feasible solution using an approximation method.

***Loop Discovery Algorithm**

1. Identify all allowable movements (vertically/horizontally) from each non-empty cell to other non-empty cells.
2. Remove cells with only 1 movement possibility. These are endpoints.
3. Remove cells that do not allow turning. These are cells between other cells.
4. Repeat steps 2 and 3 until no changes occur.
5. The remaining cells are the path of the cycle.

Minimum Delivery Limitation

This limitation requires that a minimum delivery be made between a specific supplier and demander. Mathematically it has the following structure.

$$DelMin_{sd} \geq \alpha$$

Where:

$DelMin_{sd}$ = Minimum deliver amount for path [s,d]

s = index of supplier

d = index of demander

This problem is solved by modifying the original problem and follows a modified solution logic, involving three steps.

- 1.) For each specified minimum delivery at [s,d].
 - a. Remove the amount from supply
 - b. Remove the amount from demand.
- 2.) Calculate the solution per a previously discussed method.
(ie North West, Minimum Cost, or Least Potentials).
- 3.) For each specified minimum delivery amount.
 - a. Add the amount to the solution at index [s,d].

Results

Manual Solution

Using the previously mentioned methods, the solution was calculated manually in excel. Below is a summary of each solution. The sum of the supply and demand

Problem Form Check:
 Supply = Demand = 64 => Balanced

Software Solution

A software program with visual interface for solving transportation problems has been created. The interface can be seen on the right (Figure 3)

Using this program, the user may enter the cost values, supply amounts, and demand amounts into a grid. After entering the costs, the user simply presses “GO” and the solutions are displayed on the right.

Minimum Delivery Requirement

The user may select the second tab, where delivery requirements may be entered (Figure 4). The user simply enters values, and again presses “GO”.

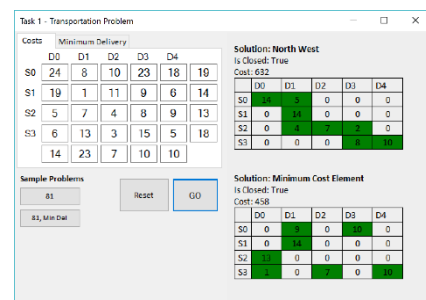

Figure 3: Transportation Problem Software

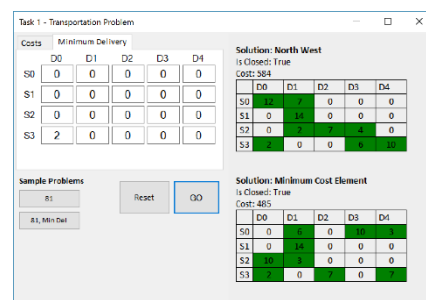

Figure 4: Minimum Delivery Adjustment

Conclusion

A transportation problem was solved by various methods, including the “North West Corner”, “Minimum Cost Element” and “Least Potentials” methods. The “North West Corner” and “Minimum Cost Element” methods are used for producing an initial approximation and the “Least Potentials” method is used for further refinement. This was demonstrated manually for each method using an example problem. Finally, the above methods were programmed into a simple-to-use interface.

Comparing the solutions for example 81, the cost values show that, in this case, the “Minimum Cost Element” outperforms the “North West” method. However the cost is able to be further reduced using the “Least Potentials” optimization.

Solution Costs

North West Corner: 632
 Minimum Cost Element: 458
 Least Potentials: 388
